QA Summary Note - DocuSign Clone (Scaler AI Labs)

Lekkala Ganesh · 29 Sep 2026 · Chrome / Chromium 153, Windows 11, 1280x960, 100% zoom · 39 confirmed bugs: 7 P1, 14 P2, 16 P3, 2 P4

Overall impression

The clone closely matches DocuSign visually and the core send path works, but several features are only surface-deep: list views are not really filtered, sorted or paginated, most field types are disabled, and settings such as signing order are not saved. Timestamps mix UTC and local time. Validation is inconsistent: some inputs are checked, others are silently accepted.

Top 5 to fix first

1. BUG-007 [P1] Agreement lists stop at 25 rows with no pagination; older envelopes are unreachable.
2. BUG-017 [P1] "Set signing order" is ignored; routing order is always stored as sequential, so envelopes reach signers in the wrong order.
3. BUG-027 [P1] Add Fields: every field type except Signature and Initial is disabled, so most real agreements cannot be prepared.
4. BUG-006 [P1] "Expiring soon" returns the same 265 envelopes as "Waiting for others" although none can expire (confirmed via API).
5. BUG-002 [P1] Start -> Envelope opens the template creator, so the main entry point starts the wrong flow.

What I tested and skipped

Tested: Home, Agreements (all folders, search, filters, sort), Set Up Envelope (upload, recipients, messages), Add Fields, Send, envelope details, global navigation, responsive widths, and seeded data, with API checks to confirm stored values. Skipped as out of scope: export/download, integrations, security testing, load testing. Not done: pixel comparison against a live DocuSign account, idle session timeout, and cancelling the OS file picker.

Suspected but not confirmed

Duplicate completed envelopes (BUG-005) exist, but double-clicking Send did not create them, so the trigger is unknown. One envelope in the API is both voided and completed. "Next: Add Fields" stalls may be server load rather than a code bug.

Assumptions

All candidates share one login (John Doe), so data created by other testers is treated as legitimate, not as a leak. Expected behaviour follows public DocuSign behaviour. Test data I created is prefixed "QALG-".
